Dental implant system

BoneTact
nanosurface

Sanatmetal 

References

The following surgical description contains general outlines for dental implantation and prosthetic activities performed with Sanat Smile system. However, the operating surgeon shall adapt the content to the patient and all other relevant factors that may have influence on the outcome of the surgery.

Therefore, Sanatmetal Ltd. strongly recommends participation on workshops and trainings prior to the initial operation.

1 | Introduction

Sanat Smile implant and instrument system ensures the satisfaction of dental surgeons and patients by combining the development trends of the most modern dental implantation market with a unique surface. The size and shape selection of the implants and the prosthetics abutments applicable on the whole indication field make the system versatile while the usage of the instrumentation is simple and straightforward.

1.1 | Outer structure of the implants

- Compression make
- Double conical shape
- Double micro-groove
- Variable width thread tip
- Spiral holes
- Apical cutting edges
- Micro grooves on the neck area
- Outstanding osseointegration

Sanat Smile Nexus

- Double lead thread
- Pitch: 2,1÷2,7 mm
- For soft bone

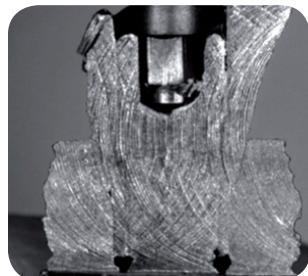

Sanat Smile Nexus-D

- Single lead thread
- Pitch: 0,65÷0,85 mm
- For hard bone

1.2 | Internal structure

The implant and the abutment are connected by an optimized internal cone. Orientation is ensured by a hexagon under the cone. The connecting screw has a peg ending to block loosening.

Platform switching implants block the microbial and mechanical irritation in the tissues around the implant thus ensuring the maximum tissue stability free from micro-movements and bacteria.

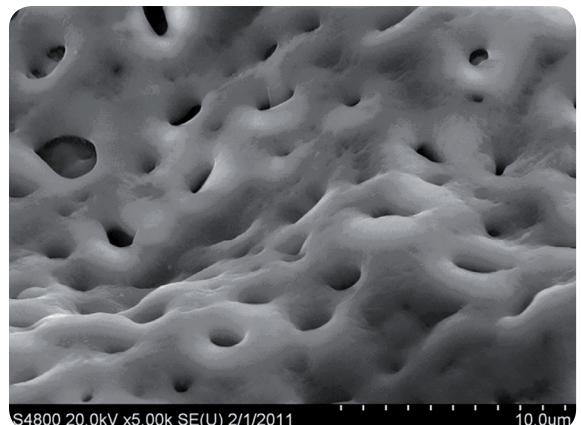

1.3 | Surface

The Bone Tact surface of the implants ensure fast and effective osseointegration.

Surface formation takes place in multiple steps. First the surface is roughened by biocompatible materials. The residual material is removed by a high temperature acidic surface cleaning. Then with an anodization system unique in Hungary a special nanosurface is created by a porotic TiO₂ ceramic layer. The surface apart from the high osseointegration properties blocks the movement of Titanium ions which could lead to implant loss.

Sanat Smile implant surface has the best properties for the high degree secondary stability:

- Surface roughness Ra=1,4 micron
- Size of nanopores 3-4 micron
- Extraordinarily clean surface

Surface cleanliness and roughness was investigated by an independent, internationally recognized research institute.

1 | Introduction

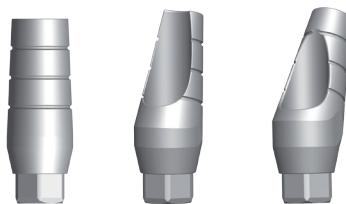

1.4 | Abutments

Free variability

Sanat Smile abutments can be used for any implant size thus the operation is fastened, simplified, moreover the stock can be reduced.

Thin wall abutments

- Straight, 15° and 25° angle correction

Anatomic abutments

- Straight, 15° and 25° angle correction
- Anodized to gingiva color. Implant is not visible even if the gingiva recedes.

Universal abutments

- For large angular correction

Screw retained abutments

Straight screw retained head

Rotation secure straight head

Multi unit base and head

Ball head abutments

- For removable dentures

1.5 | Static and fatigue testing

- In internationally recognized laboratory
- Fatigue testing: ISO 14801:2007
- Static testing
- Dynamic investigation: maximum load 275N – compares to the competitive companies.
- Supplementary investigation after the dynamic testing: torque loss of the connecting screw is 33% on average, never causing loosening.

1.6 | Packaging

- Color coded sterile packaging
- Easy to handle because of the holding unit
- Allows fast implantation
- Contains the color coded closing screw

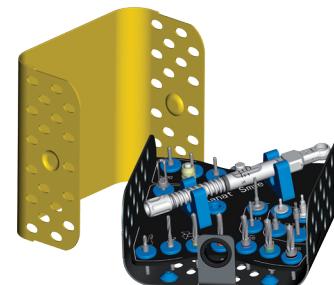

1.7 | Instruments

- Instrumentation meets all requirements
- Simple, segmented grouping
- Compact size
- Fixation with silicone inserts for more effective sterilization

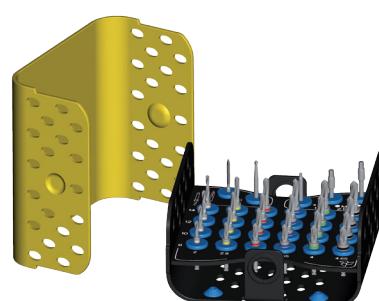

Base instrument set

- All instruments needed for implantation
- Precise-setting torque wrench
- Drillbits according to diameter, lengths marked by milling

Auxiliary instruments

- Drillbits according to diameter and length
- Motor drives, round drill, direction drill, parallel guide, etc.

1.8 | Indications

- Lack of one or more teeth
- Short line space deficiency
- Total toothlessness

Basic requirements

- Appropriate bone structure
- Good health condition
- Oral hygiene

3 | Surgical procedure

3.1 | Implant insertion

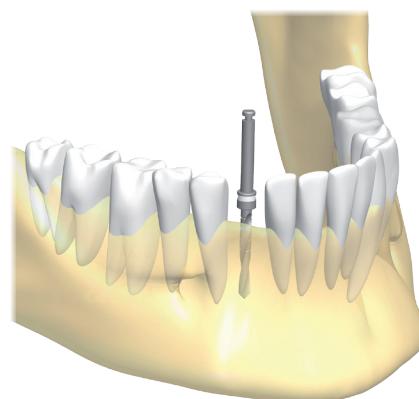

3.1.1 | Determining implant position

After the preparations mark the position of the implant with a 2,3 mm round drill or direction drill.

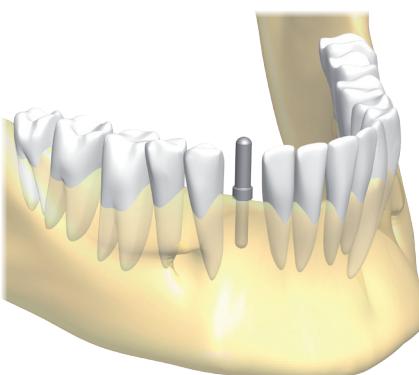

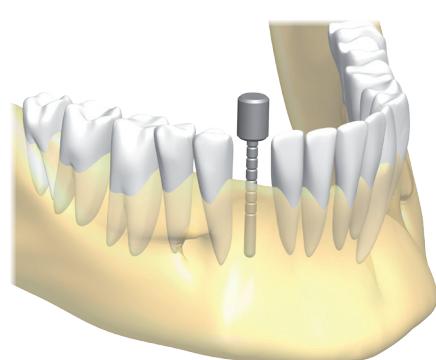

3.1.2 | Pre-drilling

Drill with the white 2 mm drillbit in the depth corresponding the length of the implant. The depth is indicated on the drillbit by marks.

3.1.3 | Depth and direction control

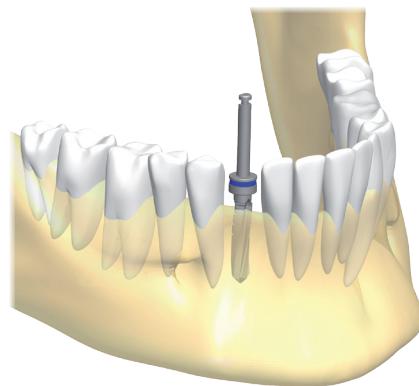

After drilling check the depth and the direction of the hole.

3.1.4 | Drilling

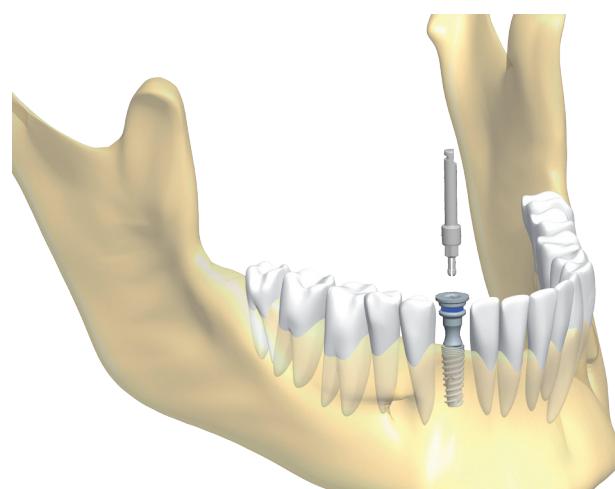

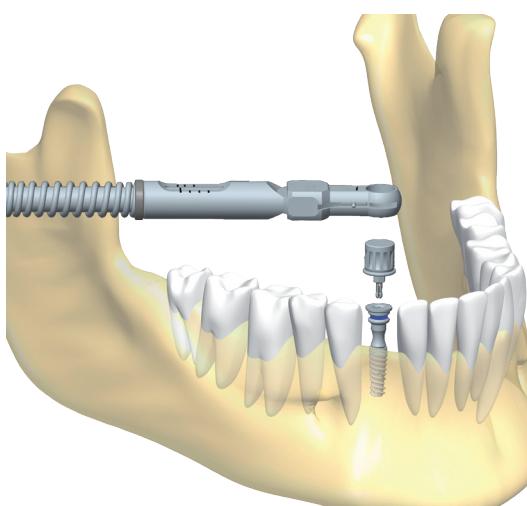

Final drilling is made with the drillbit according to the size of the implant.

The necessary drillbit is selected according to color coding on the internal surface of the implant and the packaging. The final diameter is reached step by step. If the bone structure requires deviation from this is allowed. If the bone is hard the upper third of the hole can be drilled with a drillbit one size larger. Before drilling till the whole depth remove the drillbit so that bone fragments could leave the hole.

3.1.5 | Implant positioning

Remove the implant from the glass tube and with the holding unit drive it into the prepared hole. Use ratcheting torque wrench or machine allen key.

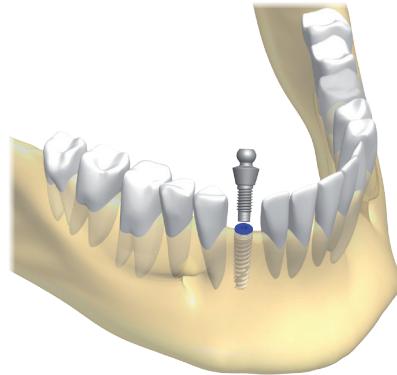

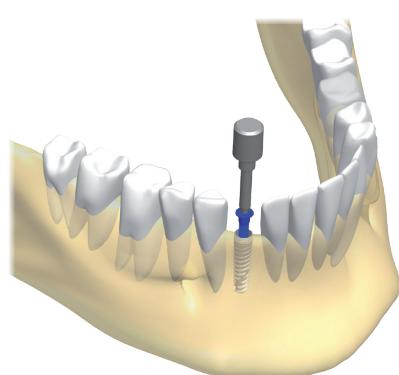

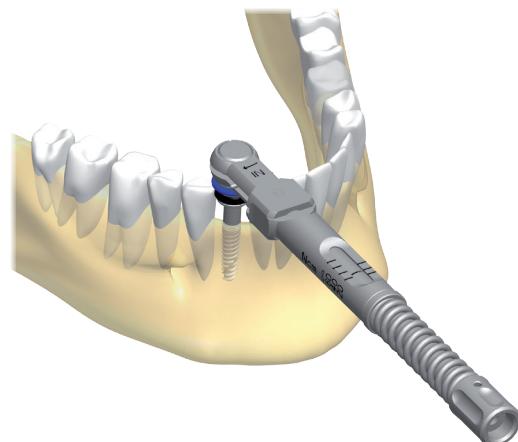

3 | Surgical procedure

3.1 | Implant insertion

3.1.6 | Driving in the implant

Connect the holding unit to the ratcheting wrench. The 2,5 mm hexagon insert can also be used. For single step implantation use the torque limiting wrench. The torque shall be 30 Ncm which is to be set prior to insertion. The instruments contain the inserting tools used with a motor. With single step implantation continue at 3.1.8. After the insertion of the implant drive in the color coded closing screw with the 1,3 mm inserting tool. Hand tighten only.

3.1.7 | Gingiva closure

Close the gingiva with any of the known methods.

3.1.8 | Gingiva forming

The requested shape can be formed with a forming head. In a single step implantation immediately, in the double step technique after the osseointegration.

3.2.1 | Preparation

After sampling the technician prepares the crown for the selected head.

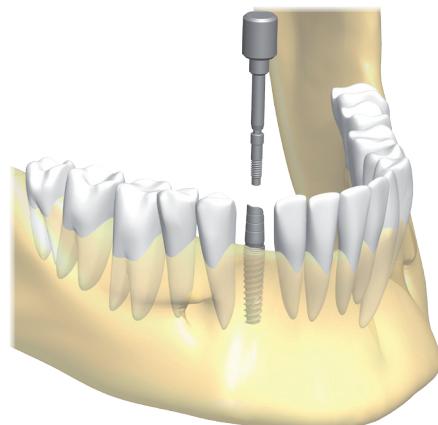

3.2.2 | Connecting the abutment

After the preparation of the gingiva the abutment shall be connected to the implant. Orientation is done by the internal hexagon. The conical connection is made by a downward movement.

3.2.3 | Securing the abutment

To secure the abutment use the connecting screw which is packed together with the abutment.

For the insertion use the 1,3 mm hexagon tool. Apply 30 Ncm torque for appropriate closing.

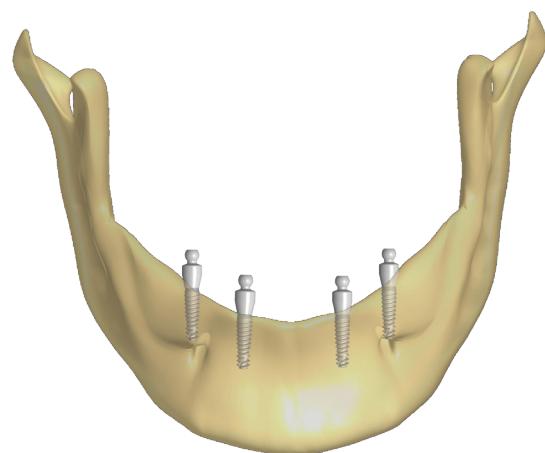

3 | Surgical procedure

3.3 Ball retention abutment fixation

3.3.1 | Ball retention abutment fixation

After the gingiva formation the ball retention abutment shall be screwed into the implant. Use the 1,3 mm hexagonal insertion tool. Apply 20 Ncm torque for appropriate closing.

3.4.1 | Preparation

The tray shall be selected so that the impression head screws shall be reachable and adequate amount of impression material be around the screws. This way the impression heads cannot interfere with the tray.

3.4.2 | Insertion and fixation of impression head

Remove the closing screw or the gingiva forming head from the implant. Insert and fix the impression head to the implant with the impression screw. The impression screw shall be tightened with the 1,3 mm hand allen key. Hand tighten only.

3.4.3 | Impressing

Check the proper fit of the tray. Fill the tray with impression material and put it into its place. Before insertion cast the impression heads around. Wait until the material sets.

3.4.4 | Impression removal

Losen and remove impression screw and also remove the impression. Close the implant.

3.4.5 | Modelling

Connect the technical analogue to the head in the impression. Fix this with the impression screw. Hand tighten only. Afterwards cast the impression with modelling material and wait until it sets.

3.4.6 | Preparation of prosthetics

After the removal of the impression head the prosthetic works can commence by attaching the selected abutment to the technical analogue.
